--Abstract

The method is for sending messages over secure communication links in networks with a mobile terminal and at least one other terminal. A secure communication link is established between a given initial network address of the mobile terminal and the address of the other terminal. The secure communication link defines at least the addresses of the two terminals. The secure communication link supports an encapsulation method to overcome network address translations and/or other translations. When the mobile terminal moves from an initial network address to a new network address, a request message is sent from the mobile terminal to the other terminal to change the secure connection to be between the new address of the mobile terminal and the other terminal. The request is sent using said method to overcome network translations. The other terminal responds to the mobile terminal with a reply message with a description about the overcoming methods supported by the other terminal. messages are thereafter sent from the mobile terminal to the other terminal by using the information sent with said reply.-
